cooperative game theory is a branch of micro economics that studies the behavior of self interested agents in strategic settings where binding agreements among agents are possible our aim in this book is to present a survey of work on the computational aspects of cooperative game theory we begin by formally defining transferable utility games in characteristic function form and introducing key solution concepts such as the core and the shapley value we then discuss two major issues that arise when considering such games from a computational perspective identifying compact representations for games and the closely related problem of efficiently computing solution concepts for games we survey several formalisms for cooperative games that have been proposed in the literature including for example cooperative games defined on networks as well as general compact representation schemes such as mc nets and skill games as a detailed case study we consider weighted voting games a widely used and practically important class of cooperative games that inherently have a natural compact representation we investigate the complexity of solution concepts for such games and generalizations of them we briefly discuss games with non transferable utility and partition function games we then overview algorithms for identifying welfare maximizing coalition structures and methods used by rational agents to form coalitions even under uncertainty including bargaining algorithms we conclude by considering some developing topics applications and future research directions
